

# Introduction to JavaScript 30- Day Challenge: Day 2

In this second day of the JavaScript 30-Day Challenge, we dive deeper into JavaScript fundamentals by exploring two exciting coding exercises: "To Be Or Not To Be" and "Counter ||".

```
let subjectAverage;  
query(  
  "SELECT * FROM marks WHERE subject_ID=" + subject  
function (datasetsWithSubject) {  
  if (datasetsWithSubject.length > 0) {  
    subjectAverage = 0;  
    datasetsWithSubjectLength = datasetsWithSubject.length;  
    datasetsWithSubject.forEach((dataset) => {  
      subjectAverage += parseFloat(dataset[0]);  
    });  
    subjectAverage =  
      subjectAverage / datasetsWithSubjectLength;  
  } else {  
    subjectAverage = 0;  
  }  
}
```

# Additional Operators

Meaning	Example
	<code>5 &lt; 2</code>
	<code>5 &gt; 2</code>
equal to	<code>5 &lt;=</code>
greater than or equal to	<code>5 &gt;=</code>
	<code>5 ===</code>
	<code>5 !==</code>
and same type	<code>5 ===</code>
	<code>5 ===</code>
true or Not	<code>5 !==</code>
	<code>5 !==</code>

## To Be Or Not To Be

### Equality Check

Develop a function "expect" that verifies if two values are strictly equal (`===`) or not equal (`!==`).

### Throw Errors

The function should throw custom errors if the values are not equal or equal, providing clear feedback to the developer.

### Test Code Easily

This challenge helps developers write more robust and reliable code by providing a simple testing utility.

# Two Methods for "expect"

## Method 1

Use arrow functions and ternary operators to implement the "expect" function in a concise manner.

## Method 2

Implement the "expect" function using traditional conditional statements for a more verbose but perhaps clearer approach.

## Comparing Approaches

Both methods achieve the same result, showcasing the flexibility of JavaScript in solving problems.

# Method : 1

```
var expect = function(val) {  
  return{  
  
    toBe:(value) => (value === val) ? true : (()=>{throw new Error("Not Equal")})(  
  
    notToBe: (value) => (value !== val) ? true : (()=>{throw new Error("Equal")})(  
  
    }  
  
  };  
  
  /**  
  
   * expect(5).toBe(5); // true  
  
   * expect(5).notToBe(5); // throws "Equal"  
  
   */
```

Method : 2

```
var expect = function(val) {  
  return{  
    toBe:(value) =>{  
      if(value === val){  
        return true;  
      }  
      else{  
        throw new Error("Not Equal");  
      }  
    },  
    notToBe:(value) =>{  
      if(value !== val){  
        return true;  
      }  
      else{  
        throw new Error("Equal");  
      }  
    }  
  }  
}
```

# Counter ||

## 1 Increment

The "createCounter" function should provide an "increment" method to increase the current value by 1.

## 2 Decrement

The "createCounter" function should also include a "decrement" method to decrease the current value by 1.

## 3 Reset

Additionally, the "createCounter" function should offer a "reset" method to set the current value back to the initial value.

```
state={
  products: storeProdu
}
render() {
  return (
    <React.Fragment>
      <div className
        <div clas
          <Titl
            <div
              <
                <
              </div>
            </div>
          </React.Fragment>
```

# Implementing createCounter

## 1 Closure Concept

The "createCounter" function uses a closure to maintain the current value of the counter.

## 2 Encapsulation

The internal "counter" variable is kept private, ensuring the integrity of the counter's state.

## 3 Return Object

The function returns an object with the three required methods: increment, decrement, and reset.

# Counter || Challenge

## Increment

The counter can be incremented by 1 with each call to the "increment" method.

## Decrement

The counter can be decremented by 1 with each call to the "decrement" method.

## Reset

The counter can be reset to its initial value by calling the "reset" method.

# Counter || Implementation

*init*

The initial value of the counter, passed as an argument to the

*increment()*

Increases the current value by 1 and returns the new value.

*decrement()*

Decreases the current value by 1 and returns the new value.

*reset()*

Sets the current value back to the initial value and returns the reset value.

```
var createCounter = function(init) {  
  let counter = init;  
  return {  
    increment: function(){  
      return ++counter;  
    },  
    reset: function(){  
      counter = init;  
      return counter;  
    },  
    decrement: function(){  
      return --counter;  
    }  
  };  
};
```

# Counter || Usage Examples

1

## Create Counter

Call the "createCounter" function with an initial value to get a counter object.

2

## Increment

Use the "increment" method to increase the counter's value.

3

## Reset

Call the "reset" method to set the counter back to its initial value.

4

## Decrement

Decrease the counter's value using the "decrement" method.

# Conclusion and Next Steps

This JavaScript 30-Day Challenge has covered two valuable exercises, "To Be Or Not To Be" and "Counter ||", which have strengthened your understanding of JavaScript fundamentals. As you continue your JavaScript learning journey, be sure to practice these concepts and explore more advanced topics to become a skilled JavaScript developer.
